

A hosted, multi-source system built through intensive human-AI collaboration

BILL 2.0 began as a personal financial organization problem and evolved into a hosted system that combines governed data, cloud execution, APIs, databases, automated workflows, durable state and evidence-oriented validation.

The project is not presented as autonomous software engineering. AI contributed heavily to analysis, design, code and documentation; the human role centered on problem definition, prioritization, execution, QA/UAT, investigation, evidence review and final acceptance.

WHAT EXISTS NOW

Hosted product + governed execution

- Product Workbench with governed commands, private read boundaries and durable product state.
- Financial flows spanning Ledger, accounting, valuation, PnL, performance, attribution and reconciliation.
- Hosted historical reconstruction and hypothetical backtesting, kept separate from the current financial profile.
- Governed pre-Ledger intake from Binance data, qualified end-to-end without treating the browser as financial authority.
- Versioned contracts, tests, receipts and machine-readable evidence used to qualify changes and preserve historical learning.

PUBLIC SIMPLIFIED VIEW

From source data to verified product state

Qualified product state

Latest successful results remain readable; failures and stale inputs are surfaced explicitly.

CORE DESIGN PRINCIPLE

A technically green result is not enough.

Implementation, evidence and intended behavior are treated as separate questions. A change is accepted only when the evidence supports the behavior that was actually intended.

HOW THE METHOD EVOLVED

Failures become reusable knowledge

- 1 Define intent**
Expected behavior, constraints and acceptance criteria.
- 2 AI-assisted implementation**
Use AI for analysis, design, code and documentation.
- 3 Challenge the output**
Targeted, behavioral and regression tests plus operational checks.
- 4 Inspect evidence**
Logs, durable records, readback, receipts and reproducible results.
- 5 Accept, reject or refine**
Separate root cause from surface symptoms before closure.
- 6 Externalize the learning**
Convert recurring failures into tests, guardrails, contracts or procedures.

TRANSFERABLE SKILLS

Problem decomposition • Data quality • QA/UAT • Failure investigation • Documentation • Workflow design • Process improvement

Example of the private engineering environment. Public material intentionally omits credentials, private URLs, deployment identities and operational secrets.

MY ROLE

Problem definition; prioritization; incremental evolution; operational execution; QA/UAT; investigation of failures; critical review of AI proposals; evidence review; final acceptance.

BOUNDARIES

Personal project in active development. Not presented as a commercial product, regulated service, official accounting system, or proof of autonomous professional software engineering. AI-assisted implementation is substantial and explicitly acknowledged.
